PLANAR GRAPHS ARE 9/2-COLORABLE

DANIEL W. CRANSTON AND LANDON RABERN

Abstract. We show that every planar graph $G$ has a 2-fold $9$-coloring. In particular, this implies that $G$ has fractional chromatic number at most $\frac{9}{2}$. This is the first proof (independent of the 4 Color Theorem) that there exists a constant $k < 5$ such that every planar $G$ has fractional chromatic number at most $k$.

1. Introduction

To fractionally color a graph $G$, we assign to each independent set in $G$ a nonnegative weight, such that for each vertex $v$ the sum of the weights on the independent sets containing $v$ is $1$. A graph $G$ is fractionally $k$-colorable if $G$ has such an assignment of weights where the sum of the weights is at most $k$. The minimum $k$ such that $G$ is fractionally $k$-colorable is its fractional chromatic number, denoted $\chi_f(G)$. (If we restrict the weight on each independent set to be either $0$ or $1$, we return to the standard definition of chromatic number.) In 1997, Scheinerman and Ullman [12, p. 75] succinctly described the state of the art for fractionally coloring planar graphs. Not much has changed since then.

The fractional analogue of the four-color theorem is the assertion that the maximum value of $\chi_f(G)$ over all planar graphs $G$ is $4$. That this maximum is no more than $4$ follows from the four-color theorem itself, while the example of $K_4$ shows that it is no less than $4$. Given that the proof of the four-color theorem is so difficult, one might ask whether it is possible to prove an interesting upper bound for this maximum without appeal to the four-color theorem. Certainly $\chi_f(G) \leq 5$ for any planar $G$, because $\chi(G) \leq 5$, a result whose proof is elementary. But what about a simple proof of, say, $\chi_f(G) \leq \frac{9}{2}$ for all planar $G$? The only result in this direction is in a 1973 paper of Hilton, Rado, and Scott [6] that predates the proof of the four-color theorem; they prove $\chi_f(G) < 5$ for any planar graph $G$, although they are not able to find any constant $c < 5$ with $\chi_f(G) < c$ for all planar graphs $G$. This may be the first appearance in print of the invariant $\chi_f$.

In Section 2 we give exactly what Scheinerman and Ullman asked for—a simple proof that $\chi_f(G) \leq \frac{9}{2}$ for every planar graph $G$. In fact, this result is an immediate corollary of a stronger statement in our main theorem. Before we can express it precisely, we need another definition. A $k$-fold $\ell$-coloring of a graph $G$ assigns to each vertex a set of $k$ colors, such that adjacent vertices receive disjoint sets, and the union of all sets has size at most $\ell$. If $G$ has
a $k$-fold $\ell$-coloring, then $\chi_f(G) \leq \frac{\ell}{k}$. To see this, consider the $\ell$ independent sets induced by the color classes; assign to each of these sets the weight $\frac{1}{k}$. Now we can state the theorem.

**Main Theorem.** Every planar graph $G$ has a 2-fold 9-coloring. In particular, $\chi_f(G) \leq \frac{9}{2}$.

In an intuitive sense, the Main Theorem sits somewhere between the 4 Color Theorem and the 5 Color Theorem. It is certainly implied by the former, but it does not immediately imply the latter. The Kneser graph $K_{n,k}$ has as its vertices the $k$-element subsets of $\{1, \ldots, n\}$ and two vertices are adjacent if their corresponding sets are disjoint. Saying that a graph $G$ has a 2-fold 9-coloring is equivalent to saying that it has a homomorphism to the Kneser graph $K_{9,2}$. To claim that a coloring result for planar graphs is between the 4 and 5 Color Theorems, we would like to show that every planar graph $G$ has a homomorphism to a graph $H$, such that $H$ has clique number 4 and chromatic number 5. Unfortunately, $K_{9,2}$ is not such a graph. It is easy to see that $\omega(K_{n,k}) = \lfloor n/k \rfloor$; so $\omega(K_{9,2}) = 4$, as desired. However, Lovász [8] showed that $\chi(K_{n,k}) = n - 2k + 2$; thus $\chi(K_{9,2}) = 9 - 2(2) + 2 = 7$. Fortunately, we can easily overcome this problem.

The categorical product (or universal product) of graphs $G_1$ and $G_2$, denoted $G_1 \times G_2$ is defined as follows. Let $V(G_1 \times G_2) = \{(u,v) | u \in V(G_1) \text{ and } v \in V(G_2)\}$; now $(u_1, v_1)$ is adjacent to $(u_2, v_2)$ if $u_1 u_2 \in E(G_1)$ and $v_1 v_2 \in E(G_2)$. Let $H = K_5 \times K_{9,2}$. It is well-known [5] that if a graph $G$ has a homomorphism to each of graphs $G_1$ and $G_2$, then $G$ also has a homomorphism to $G_1 \times G_2$ (the image of each vertex in the product is just the products of its images in $G_1$ and $G_2$). The 5 Color Theorem says that every planar graph has a homomorphism to $K_5$; so if we prove that every planar graph $G$ has a homomorphism to $K_5$, then we also get that $G$ has a homomorphism to $K_5 \times K_{9,2}$.

It is easy to check that for any $G_1$ and $G_2$, we have $\omega(G_1 \times G_2) = \min(\omega(G_1), \omega(G_2))$ and $\chi(G_1 \times G_2) \leq \min(\chi(G_1), \chi(G_2))$. To prove this inequality, we simply color each vertex $(u, v)$ of the product with the color of $u$ in an optimal coloring of $G_1$, or the color of $v$ in an optimal coloring of $G_2$. (It is an open problem whether this inequality always holds with equality [14].) When $H = K_5 \times K_{9,2}$ we get $\omega(H) = 4$ and $\chi(H) = 5$. Earlier work of Naserasr [9] and Nešetřil and Ossona de Mendez [10] also constructed graphs $H$, with $\omega(H) = 4$ and $\chi(H) = 5$, such that every planar graph $G$ has a homomorphism to $H$; however, their examples had more vertices than ours. Naserasr gave a graph with size $63(\binom{9}{2}) = 35, 144, 235$ and the construction in [10] was still larger. In contrast, $|K_5 \times K_{9,2}| = 5(\binom{9}{2}) = 180$.

Wagner [13] characterized $K_5$-minor-free graphs. The Wagner graph is formed from an 8-cycle by adding an edge joining each pair of vertices that are distance 4 along the cycle. Wagner showed that every maximal $K_5$-minor-free graph can be formed recursively from planar graphs and copies of the Wagner graph by pasting along copies of $K_2$ and $K_3$ (see also [4, p. 175]). Since the Wagner graph is 3-colorable, it clearly has a 2-fold 9-coloring. To show that every $K_5$-minor-free graph is 2-fold 9-colorable, we color each smaller planar graph and copy of the Wagner graph, then permute colors so that the colorings agree on the vertices that are pasted together.

Hajós conjectured that every graph is $(k - 1)$-colorable unless it contains a subdivision of $K_k$. This is known to be true for $k \leq 4$ and false for $k \geq 7$. The cases $k = 5$ and $k = 6$ remain unresolved. Since this problem seems difficult, we offer the following weaker conjecture.
**Conjecture.** Every graph with no $K_5$-subdivision is 2-fold 9-colorable.

An immediate consequence of the 4 Color Theorem is that every $n$-vertex planar graph has an independent set of size at least $\frac{n}{4}$ (and this is best possible, as shown by the disjoint union of many copies of $K_4$). In 1968, Erdős [2] suggested that perhaps this corollary could be proved more easily than the full 4 Color Theorem. And in 1976, Albertson [1] showed (independently of the 4 Color Theorem) that every $n$-vertex planar graph has an independent set of size at least $\frac{2n}{9}$.

Albertson’s proof inspired and heavily influenced our proof of the Main Theorem. The bulk of the work in our proof consists in showing that certain configurations are reducible, i.e., they cannot appear in a minimal counterexample to the theorem. The proof concludes via a discharging argument, where we show that every planar graph contains one of the forbidden configurations; hence, it is not a minimal counterexample.

Before the proof, we need a few definitions. A $k$-vertex is a vertex of degree $k$; similarly, a $k^-$-vertex (resp. $k^+$-vertex) has degree at most (resp. at least) $k$. A $k$-neighbor of a vertex $v$ is a $k$-vertex that is a neighbor of $v$; and $k^-$-neighbors and $k^+$-neighbors are defined analogously. A $k$-cycle is a cycle of length $k$. A vertex set $V_i$ in a connected graph $G$ is separating if $G \setminus V_i$ has at least two components. A cycle $C$ is separating if $V(C)$ is separating. Finally, an independent $k$-set is an independent set (or stable set) of size $k$.

2. Fractional Coloring of Planar Graphs

Now we prove our Main Theorem, that every planar graph has a 2-fold 9-coloring. Our proof uses the methods of reducibility and discharging. First, we prove that certain properties must hold for every minimal counterexample to the theorem (by “minimal” we mean having the fewest vertices and, subject to that, the fewest non-triangular faces). To conclude, we give a counting argument, via the discharging method, showing that every planar graph violates one of these properties. Thus, no minimal counterexample exists, so the theorem is true.

Hereafter, we write $G$ to denote a minimal counterexample to the theorem. To remind the reader of this assumption, we will often refer to a minimal $G$. Whenever we say “a coloring”, we mean a 2-fold 9-coloring. Note that $G$ is a plane triangulation; otherwise, adding an edge contradicts our choice of $G$ as having the fewest non-triangular faces.

**Lemma 1.** A minimal $G$ has no separating clique. Specifically, $G$ has no separating 3-cycle.

**Proof.** Suppose $G$ has a separating clique $X$ and let $C_1, \ldots, C_k$ be the components of $G \setminus X$. By minimality of $|G|$, we have colorings of $G[V(C_i) \cup X]$ for each $i \in \{1, \ldots, k\}$. Permute the colors on each subgraph $G[V(C_i) \cup X]$ so the colorings agree on $X$. Now identifying the copies of $X$ in each $G[V(C_i) \cup X]$ gives a coloring of $G$, a contradiction. \hfill $\square$

Although it was easy to prove, Lemma [1] will play a crucial role in our proof. We will often want to identify two neighbors $u_1$ and $u_2$ of a vertex $v$ and color the smaller graph by minimality. To do so, we must ensure that $u_1$ and $u_2$ are indeed non-adjacent; these arguments typically use the fact that if $u_1$ and $u_2$ were adjacent, then $u_1u_2v$ would be a separating 3-cycle.
Lemma 2. A minimal $G$ has minimum degree 5.

Proof. Since $G$ is a plane triangulation, it has minimum degree at least 3 and at most 5. If $G$ contains a 3-vertex, then its neighbors induce a separating 3-cycle, contradicting Lemma 1. If $G$ contains a 4-vertex $v$, then some pair of its neighbors are non-adjacent, since $K_5$ is non-planar. Form $G'$ from $G$ by deleting $v$ and contracting a non-adjacent pair of its neighbors. Color $G'$ by minimality, then lift the coloring back to $G$; only $v$ is uncolored. Since two of $v$'s neighbors have the same colors, we can extend the coloring to $G$. □

The following fact will often allow us to extend a 2-fold 9-coloring to the uncolored vertices of an induced $K_{1,3}$. It will be useful in verifying that numerous configurations are forbidden from a minimal $G$. We will also often apply it when the uncolored subgraph is simply $P_3$.

Fact 1. Let $H = K_{1,3}$. If each leaf has a list of size 3 and the center vertex has a list of size 5, then we can choose 2 colors for each vertex from its lists such that adjacent vertices get disjoint sets of colors.

Proof. Let $v$ denote the center vertex and $u_1, u_2, u_3$ the leaves. Since $2|L(v)| > |L(u_1)| + |L(u_2)| + |L(u_3)|$, some color $c \in L(v)$ appears in $L(u_i)$ for at most one $u_i$. If such a $u_i$ exists, then by symmetry, say it is $u_1$; now color $v$ with $c$ and some color not in $L(u_1)$. Otherwise color $v$ with $c$ and an arbitrary color. Now color each $u_i$ arbitrarily from its at least 2 available colors. □

We use the same approach to prove each of Lemmas 3, 4, and 5. Our idea is to contract some edges of $G$ to get a smaller planar graph $G'$, which we color by minimality. In particular, in $G'$ we identify some pairs of non-adjacent vertices of $G$ that each have a common neighbor. When we lift the coloring of $G'$ to $G$ this means that some of the uncolored vertices will have neighbors with both colors the same, reducing the number of colors used on the neighborhood of each such uncolored vertex.

One early example of this technique is Kainen’s proof [7] of the 5 Color Theorem. If $G$ is a planar graph, then by Euler’s Theorem, $G$ has a $5^-$-vertex $v$. If $d(v) \leq 4$, then we 5-color $G - v$ by minimality; now, since $d(v) \leq 4$, we can extend the 5-coloring to $v$. Suppose instead that $d(v) = 5$. Since $K_6$ is non-planar, $v$ has two neighbors $u_1$ and $u_2$ that are non-adjacent; form $G'$ by contracting the edges $vu_1$ and $vu_2$, and again 5-color $G'$ by minimality. To extend the 5-coloring to $v$, we note that even though $d(v) = 5$, at most four colors appear on the neighbors of $v$ (since $u_1$ and $u_2$ have the same color). This completes the proof.

Because a minimal $G$ has no separating 3-cycles, if vertices $u_1$ and $u_2$ have a common neighbor $v$ and do not appear sequentially on the cycle induced by the neighborhood of $v$, then $u_1$ and $u_2$ are non-adjacent. The numeric labels in the figures denote pairs (or more) of vertices that are identified in $G'$ when we delete any vertices labeled $v$, $u_1$, $u_2$ or $u_3$; vertices with the same numeric label get identified.

Typically, it suffices to verify that the vertices receiving a common numeric label are pairwise nonadjacent. One potential complication is if two vertices that are drawn as distinct are in fact the same vertex. This usually cannot happen if the vertices have a common neighbor $v$, since then the degree of $v$ would be too small. Similarly, it cannot happen if they are joined by a path of length three, since then we would get a separating 3-cycle.
For 4-coloring, Birkhoff [3] showed how to exclude separating 4-cycles and 5-cycles. Excluding separating 4-cycles would simplify our arguments below since we would not need to worry about vertices at distance at most four being the same. The proof excluding 4-cycles for 4-coloring is quite easy, but it does not work in our context because standard Kempe chain arguments break down for 2-fold coloring. The problem is illustrated in Figure 1. Figure 1(A) shows the situation for 1-fold coloring; here the 13-path blocks the 24-path. Figure 1(B) shows the situation for 2-fold coloring, here the 24-path can get through because on the 13-path, a vertex has color 2 as well as color 1.

![Figure 1](image-url)

(A) The 2, 4-path is blocked by the 1, 3-path. (B) The 2, 4-path gets through.

**Figure 1.** The problem with Kempe chains for 2-fold coloring.

**Lemma 3.** A minimal $G$ has no 5-vertex with a 5-neighbor and a non-adjacent 6-neighbor.

**Proof.** We first consider the case where a 5-vertex $v$ has non-adjacent 5-neighbors $u_1$ and $u_2$, as shown in Figure 2(A). We color $G'$ by minimality, then lift the coloring to $G$. (Recall that to form $G'$, we delete $v$ and all $u_i$ and for each pair (or more) of vertices with the same label, we identify them.) Now in $G$ each $u_i$ has a list of at least 3 colors and $v$ has a list of at least 5 colors; so, by Fact 1, we can extend the coloring to $G$.

Now we consider the case where a 5-vertex $v$ has a 5-neighbor and a 6-neighbor that are non-adjacent, as shown in Figure 2(B). Again, when we lift the coloring of $G''$ to $G$, $v$ has a list of size 5 and each of its uncolored neighbors has a list of size 3. Hence, by Fact 1 we can extend the coloring of $G'$ to $G$. Here no pair of labeled vertices can be identified, since each such pair is drawn at distance three or less (and $G$ has no separating 3-cycle).

**Lemma 4.** A minimal $G$ has no 6-vertex with non-adjacent 6-neighbors.

**Proof.** Let $v$ be a 6-vertex with two non-adjacent 6-neighbors, $u_1$ and $u_2$. We have three possibilities for the degrees of these 6-neighbors: two 5-vertices, a 5-vertex and a 6-vertex, and two 6-vertices. For each choice of degrees for the $u_i$s, we have two possibilities for their relative location; they could be “across” from each other (at distance three along the cycle induced by the neighbors of $v$) or “offset” from each other (at distance two along the same
(a) A 5-vertex, \(v\), with non-adjacent 5-neighbors, \(u_1\) and \(u_2\).

(b) A 5-vertex, \(v\), with a non-adjacent 5-neighbor, \(u_1\), and 6-neighbor, \(u_2\).

Figure 2. The cases of Lemma 3.

(a) A 6-vertex, \(v\), with non-adjacent 5-neighbors, \(u_1\) and \(u_2\), that are across from each other.

(b) A 6-vertex, \(v\), with a non-adjacent 5-neighbor, \(u_1\), and 6-neighbor, \(u_2\), that are across from each other.

(c) A 6-vertex, \(v\), with non-adjacent 6-neighbors, \(u_1\) and \(u_2\), that are across from each other.

Figure 3. The “across” cases of Lemma 4.

This yields a total of six possibilities; the three across possibilities are shown in Figure 3 and the three offset possibilities are shown in Figure 4.

In Figures 3(A,B), all of the vertices with numeric labels (those that will be identified in \(G'\)) must be distinct, since they are drawn within distance three of each other. The only complication is in Figure 3(C): a vertex labeled 1 might be the same as a vertex labeled 4 that is drawn at distance four; call this vertex \(x\). By symmetry, assume that \(x\) is formed by identifying the vertex in the top left labeled 1 and the vertex in the bottom right labeled 4. This is only a problem if also a vertex labeled 1 is adjacent to one labeled 4; so suppose this
happens. Note that the vertex in the top right labeled 4 cannot be adjacent to the vertex in the bottom left labeled 1; they are on opposite sides of the cycle $xu_1vu_2$. So, again by symmetry, we assume that $x$ is adjacent to the vertex in the bottom left labeled 1. However, now we have a separating 3-cycle (consisting of $x$, its neighbor labeled 1, and their common neighbor $u_1$); this contradicts Lemma 1. This contradiction finishes the across cases.

Now we consider the three offset cases, which are shown in Figure 4. As with the across cases, in Figures 4(A,B), all of the vertices with numeric labels must be distinct, since they are drawn within distance 3 of each other.

The only complication in is the third case, shown in Figures 4(C,D): the vertices labeled 1 and 3 that are drawn at distance four in Figure 4(C) might be the same; if so, then call this vertex $x$. In this case we switch to the identifications shown in Figure 4(D); we omit from Figure 4(D) a few edges incident to $x$, to keep the picture pretty. Now all vertices with numeric labels are at distance at most three, due to the extra edges incident to $x$. Also, the two vertices labeled 1 that are drawn at distance three are non-adjacent, since they are separated by cycle $u_1vu_2x$. This finishes the offset cases.

\[\square\]
Lemma 5. A minimal $G$ has no 7-vertex with a 5-neighbor and two other 6-neighbors such that all three are pairwise non-adjacent.

Proof. Figure 5(A) shows a 7-vertex with three pairwise non-adjacent 5-neighbors. Here, all pairs of vertices with numeric labels are at distance at most three, so they must be distinct.

In Figure 5(B), all pairs of vertices with numeric labels are again at distance at most three, except for one vertex labeled 1 which is drawn at distance four from each vertex labeled 3. The only possible problem is if one pair of vertices labeled 1 and 3 are actually the same vertex, while another pair labeled 1 and 3 are adjacent; these pairs must be disjoint, since otherwise we have a separating 3-cycle. The pair that are adjacent must be drawn at distance at least three, to avoid a separating 3-cycle. Hence, we need only consider the case where the vertices labeled 1 and 3 drawn at distance three are adjacent, and the other pair labeled 1 and 3 are the same vertex $x$. However, this is impossible, since then the adjacent pair are on opposite sides of the cycle $u_1v_3x$.

In Figure 5(C), all pairs of vertices with numeric labels are at distance at most three, so they must be distinct.

Consider Figure 5(D). None of the vertices labeled 3 can be the same as any other numerically labeled vertices since they are all distance at most 3 apart. Similarly, none of the vertices labeled 1 and 2 can be the same. So we need only consider the case that vertices labeled 4 are the same as those labeled 1 or 2. If a pair of vertices labeled 2 and 4 are the same, then it must be the pair that are drawn at distance 4; call this vertex $x$. In this case, we unlabel the vertices labeled 4 and label $w_3$ with 3. Now, thanks to $x$, all labeled vertices are distance at most three apart; hence, they must be distinct. So we may assume that vertices labeled 4 are not the same as those labeled 2.

Suppose instead that a vertex labeled 4 is the same as one labeled 1; call this vertex $y$. This is only a problem if also some pair of vertices labeled 1 and 4 are adjacent. But this is impossible as follows. Since the pair of vertices labeled 1 have a common neighbor, they cannot be adjacent; similarly for the pair labeled 4. So the pairs that are identified and adjacent must be disjoint. Further, the identified pair must contain the rightmost vertex labeled 1. If it is identified with the bottom vertex labeled 4, then the remaining vertices cannot be adjacent, since they are on opposite sides of the 4-cycle $u_1v_4y$. If it is identified with the top vertex labeled 4, then the remaining pair cannot be adjacent, since they have a common neighbor.

Finally, consider Figure 5(E). By horizontal symmetry (and planarity), we assume that the vertices labeled 2 that are drawn at distance three are indeed non-adjacent; furthermore, we can assume that the vertices labeled 1 and 2 that are drawn at distance four are distinct. If not, then we reflect across the edge $w_2v$. Hence, in forming $G'$ we can contract the vertices labeled 2 to a single vertex (we can also contract the vertices labeled 3 to a single vertex). So we only need to consider the vertices labeled 1 and 4. The only possible problem is if some pair of vertices labeled 1 and 4 that are drawn at distance four are actually the same vertex $x$. Suppose this is the case. If $w_1$ and $w_3$ are distinct, then we neglect the vertices labeled 1 and 4 altogether; instead we label $w_1$ as 2 and $w_3$ as 3. Due to $x$, all pairs of vertices with numeric labels are now distance at most three. (Also, we can assume that $w_1$ is not adjacent to the vertex labeled 2 that is drawn at distance 4; if not, then we again reflect across edge
PLANAR GRAPHS ARE 9/2-COLORABLE

(e) A 7-vertex, \( v \), with a 5-neighbor, \( u_2 \), and two 6-neighbors, \( u_1 \) and \( u_3 \), with all pairs of \( u_i \)'s non-adjacent.

**Figure 5.** The five cases of Lemma 5.
Main Theorem. Every planar graph $G$ has a 2-fold 9-coloring. In particular, $\chi_f(G) \leq \frac{9}{2}$.

Proof. The second statement follows from the first, which we prove now. Let $G$ be a minimal counterexample to the theorem. We will use the discharging method with initial charge $d(v) - 6$ for each vertex $v$. We write $\text{ch}(v)$ to denote the initial charge and $\text{ch}^*(v)$ to denote the charge after redistributing. By Euler’s Formula, $\sum_{v \in V(G)} \text{ch}(v) = -12$. By assuming that $G$ satisfies the conditions stipulated in Lemmas 1–5, we redistribute the charge (without changing its sum) so that every vertex finishes with nonnegative charge. This yields the obvious contradiction $-12 = \sum_{v \in V(G)} \text{ch}(v) = \sum_{v \in V(G)} \text{ch}^*(v) \geq 0$.

We need a few definitions. For a vertex $v$, let $H_v$ denote the subgraph induced by the 5-neighbors and 6-neighbors of $v$. If some $w \in V(H_v)$ has $d_{H_v}(w) = 0$, then $w$ is an isolated neighbor of $v$; otherwise $w$ is a non-isolated neighbor. A non-isolated 5-neighbor of a vertex $v$ is crowded (with respect to $v$) if it has two 6-neighbors in $H_v$. We use crowded 5-neighbors in the discharging proof to help ensure that 7-vertices finish with sufficient charge, specifically to handle the configuration in Figure 6. We redistribute charge via the following four rules; they are applied simultaneously, wherever applicable.

(R1) Each $8^+$-vertex gives charge $\frac{1}{2}$ to each isolated 5-neighbor and charge $\frac{1}{4}$ to each non-isolated 5-neighbor.

(R2) Each 7-vertex gives charge $\frac{1}{2}$ to each isolated 5-neighbor, charge 0 to each crowded 5-neighbor and charge $\frac{1}{4}$ to each remaining 5-neighbor.

(R3) Each $7^+$-vertex gives charge $\frac{1}{4}$ to each 6-neighbor.

(R4) Each 6-vertex gives charge $\frac{1}{2}$ to each 5-neighbor.

To show that every vertex $v$ finishes with nonnegative charge, we consider $d(v)$.

$d(v) \geq 8$: We will show that $v$ gives away charge at most $\frac{d(v)}{4}$. Since $d(v) \geq 8$, we have $\text{ch}(v) = d(v) - 6 \geq \frac{d(v)}{4}$, so this will imply $\text{ch}^*(v) \geq 0$. Rather than giving away charge by rules (R1) and (R3), instead let $v$ give charge $\frac{1}{4}$ to each neighbor. Now let each isolated 5-neighbor $w$ take also the charge $\frac{1}{4}$ that $v$ gave to the neighbor that clockwise around $v$ succeeds $w$. Now each neighbor of $v$ has received at least as much charge as by rules (R1) and (R3) and $v$ has given away charge $\frac{d(v)}{4}$. Thus, when $v$ gives away charge according to rules (R1) and (R3), this charge is at most $\frac{d(v)}{4}$, so $\text{ch}^*(v) \geq 0$.

$d(v) = 7$: First, suppose that $v$ has an isolated 5-neighbor $w$. Let $x, y \in N(v)$ be the two $7^+$-vertices that are common neighbors of $v$ and $w$. We will show that the total charge that $v$ gives to $N(v) \setminus \{x, y\}$ is at most $\frac{1}{2}$. By Lemma 5, these four remaining vertices include at
most two $6^-$-vertices. So, if $v$ gives them a total of more than $1/2$, then one of them must be another isolated 5-neighbor. But now the final $6^-$-vertex must be at distance 2 from each of the previous 5-neighbors, violating Lemma 5.

So instead assume that $v$ has no isolated 5-neighbors. Thus, if $v$ loses total charge more than 1, then it must have at least five $6^-$-neighbors that receive charge from it (since they each take charge $1/4$). So assume that $|H_v|\geq 5$. This implies that $H_v$ consists of either (i) a 7-cycle or (ii) a single path or (iii) two paths. Recall from Lemma 4 that no 6-vertex has non-adjacent $6^-$-neighbors. This means that every vertex of degree 2 in $H_v$ is a 5-vertex; in other words, every vertex on a cycle or in the interior of a path in $H_v$ is a 5-vertex.

Now in each of cases (i)–(iii), $H_v$ has an independent 3-set containing at least one 5-vertex; the only exception is if $H_v$ consists of a path on two vertices and a path on three vertices, and the only 5-vertex is the internal vertex on the longer path. However, in this case the 5-vertex is a crowded neighbor of $v$, as in Figure 6, so it receives no charge from $v$. Thus, $\text{ch}^*(v) \geq 0$.

$d(v) = 6$: By Lemma 4, we know that $v$ has at most two $6^-$-neighbors (and if exactly two, then they are adjacent). Now (R3) implies that $\text{ch}^*(v) \geq 0 + 4(1/4) - 2(1/2) = 0$.

$d(v) = 5$: If $v$ has at least two $6^-$-neighbors, then $\text{ch}^*(v) \geq -1 + 2(1/2) = 0$; so assume that $v$ has at most one $6^-$-neighbor. Now if $v$ has at least four $6^+$-neighbors, then $\text{ch}^*(v) \geq -1 + 4(1/4) = 0$ (since $v$ has at most one 6-neighbor, $v$ is not a crowded neighbor for any of its 7-neighbors); so $v$ must have at least two 5-neighbors. By Lemma 3, these 5-neighbors must be adjacent and $v$ has no 6-neighbors. But now one of $v$’s three $7^+$-neighbors sees $v$ as an isolated 5-neighbor, so sends $v$ charge $1/2$. Thus, $\text{ch}^*(v) \geq -1 + 1/2 + 2(1/4) = 0$. This completes the proof.

![Figure 6](image_url) A 7-vertex $v$ gives no charge to any crowded 5-neighbor.

A natural question is whether our theorem could be strengthened to show that every planar graph has a $t$-fold $s$-coloring, for some pair $(s, t)$ with $s/t < 9/2$. Clearly, such results are true for every pair $(s, t)$ with $s/t \geq 4$, since they follow from the 4 Color Theorem (this is immediate since the Kneser graph $K_{s,t}$ contains $K_4$). However, here we note that a proof of any such result must differ significantly from the proof of the Main Theorem. In particular, we show that none of our reducibility proofs, with the exceptions of those for separating triangles and vertices of degree 4, remain valid for any pair $(s, t)$ with $s/t < 9/2$. Recall that the proofs of Lemmas 3–5 all crucially relied on Fact 1. Here we show that to prove an analogue of this fact, even for $K_{1,2}$ (rather than $K_{1,3}$) requires that $s/t \geq 9/2$. 

Suppose that a copy of $K_{1,2}$ has a $t$-fold coloring whenever the leaves, $u_1$ and $u_2$, are given lists of size $b$ and the center vertex, $v$, is given a list of size $a$. Consider the list assignment $L(u_1) = \{1, \cdots, b\}$, $L(u_2) = \{a-b+1, \cdots, a\}$, and $L(v) = \{1, \cdots, a\}$. Every $t$-fold coloring from these lists uses at most $b - (a-b) = 2b - a$ common colors on $u_1$ and $u_2$, so uses at least $2t - (2b-a)$ distinct colors on $u_1$ and $u_2$. So, to color $v$, we must have $a - (2t - (2b-a)) \geq t$, which means $b \geq \frac{3}{2}t$. Now consider an analogue of Lemma 3, 4, or 5 for $t$-fold $s$-coloring. First we contract, color the smaller graph by minimality, and lift the coloring to $G$. Now $v$ has list size $s - 2t$, and each $u_i$ has list size $s - 3t$. So we have $a = s - 2t$ and $b = s - 3t$. Now $s - 3t = b \geq \frac{3}{2}t$, so $\frac{s}{t} \geq \frac{9}{2}$.

ACKNOWLEDGMENTS

As we mentioned in the introduction, the ideas in this paper come largely from Albertson’s proof [1] that planar graphs have independence ratio at least $\frac{2}{5}$. In fact, many of the reducible configurations that we use here are special cases of the reducible configurations in that proof. We very much like that paper, and so it was a pleasure to be able to extend Albertson’s work.

The first author thanks his Lord and Savior, Jesus Christ.
